Field of the Invention The present invention relates to analog-to-digital (A/D) converters in general and, in particular, to A/D converters having a plurality of resistor divider circuits for connecting a plurality of input resistor branches to a single reference voltage source. 2. Description of the Prior Art Typical A/D converters have used a reference voltage source to provide a fixed reference level for determining the zero-point (virtual zero-potential) to which the reference voltage is compared. This reference voltage is generated by a resistor divider circuit having a plurality of resistors connected in series between a reference voltage source, such as a battery or a ground terminal, and a common input node of a comparator stage. The common node, which is normally a single node located at the output of the resistor divider, is connected to a comparator circuit for receiving an analog input signal. The analog input signal is compared to the reference voltage level, and the comparator output signal is used to control a binary counter which sequentially compares the input signal to the reference voltage. The final count of the binary counter is used to provide a digital output signal indicating the voltage level of the analog input signal at a common output node. This typical prior art resistor divider circuit has several disadvantages. One disadvantage is the size and weight associated with the small NPN transistors used in the resistor divider. Furthermore, since all of the inputs to the counter are connected to a single common node, the reference voltage can vary as a function of the number of series connected resistor divider circuits. Another disadvantage is the fact that the reference potential at the common node is not externally adjustable. It is desirable, therefore
